Annex I–V to The Role of Aid in the Provision of Sexual and Reproductive Health Services
to
The Expert Group for Aid Studies (EBA)

Jesper Sundewall is an associate professor of global health systems at Lund University and University of KwaZulu-Natal. Jesper's research is focused on health financing and health systems analysis in low- and middle-income countries.

Björn Ekman is an associate professor of global health economics at Lund University. His research interests are mainly in health and economics with a particular focus on health systems analysis and effects of digital technologies on health services.

Jessy Schmit is a public health researcher with a Master of Medical Science in Public Health (MPH) from Lund University. Her research interests lie in health economics, health financing and social determinants of health.

Annex I. Systematic review of the literature

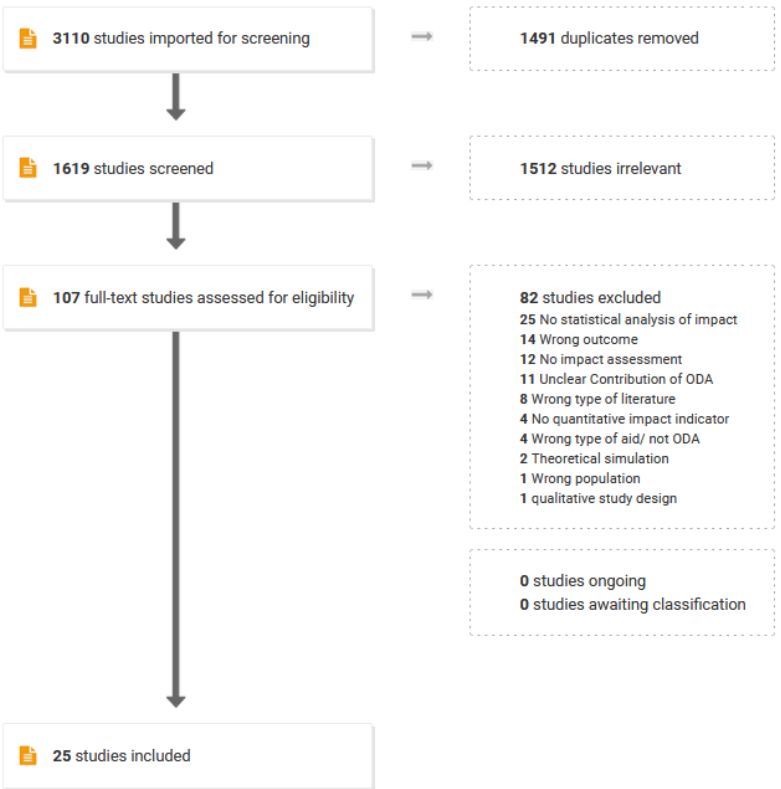
A systematic review was conducted investigating the evidence of an impact of official development assistance on sexual and reproductive health (SRH) outcomes in low-and lower-middle-income countries. Consistent with the components of SRH presented in the Guttmacher-Lancet report (Starrs et al., 2018), outcomes of interest for the review included gender-based violence, maternal and infant health (incl. ante- and postnatal care), menstrual health, abortion, HIV/AIDS, other sexually transmitted diseases, reproductive cancer, family planning and female genital mutilation (FGM).

Between 25/07/2022 and 05/08/2022, 54 databases (incl. MEDLINE, CINAHL Complete, ScienceDirect, and Scopus) and 1 preprint server (arXiv) were systematically searched for English language articles assessing the impact of official development assistance (ODA) on SRH. The search strategy combined terms for the outcomes of interest, development assistance, low- and lower-middle income countries and impact evaluation. The search was restricted to articles published between 2002 and 2020. Additional grey literature was retrieved through manual keyterm or abridged searches of the WHO IRIS database, the World Bank eLibrary, UNICEF's Office of Research-Innocenti Publications, UNFPA publications, the Joint United Nations Programme on AIDS Publications Library, the Publications Office of the European Union and the preprint servers medrxiv and Lancet preprints.

To be eligible for inclusion in the review, articles had to statistically assess the impact of ODA on at least one of the specified SRH outcomes using at least one quantitative indicator. Articles were included in the review if they were experimental, quasi-experimental or observational in study design and if aid recipients matched the target.

population, defined as low-and lower-middle-income countries according to the World Bank classification in 2002. Only English language articles published between 2002 and 2020 were included in the review. Studies exclusively assessing humanitarian assistance or projects not yet implemented were excluded, as were purely theoretical simulation or projection studies. Also excluded were articles where foreign aid was clearly non-ODA, or the contribution of ODA to overall foreign funding was unclear or negligible.

Figure A1. Prisma chart for systematic review



Screening was conducted in Covidence by two reviewers. Reviewers were blinded to each other's decisions at both title/abstract screening and full-text screening. Conflicting decisions were manually resolved by the reviewers at each screening stage before

moving onto the next stage. Subsequent data extraction was performed in Covidence by one reviewer, with the extraction template containing information on study details, study design, type and period of funding, outcomes assessed, results presented, and conclusions drawn by the authors.

Results

Of 1619 unique articles identified in the search, 25 met the eligibility criteria and were therefore included in the review. Evaluations covered ODA disbursed or committed from 1968 to 2015, with most studies analyzing the impact of funding provided between 1990 and 2010. Of studies specifying a geographic region of aid recipients, the majority (10 studies) focused on Africa, particularly sub-Saharan Africa (5 studies) and the remaining studies on Asia and specifically southeast Asia (3 studies).

Results indicate strong variation in aid definitions used (see Table A1) and outcomes evaluated. Infant health emerges as a dominant topic in the current evaluation literature, with 13 of 25 studies focused on infant mortality as an outcome. Other evaluations focused largely on HIV/AIDS (five studies) or maternal health and maternal health service provision (six studies). Three studies analyzed the impact of ODA on family planning and only one study addressed abortion as an outcome. Notably, gender-based violence, reproductive cancers, sexually transmitted diseases other than HIV/AIDS, FGM and menstrual health were absent from the results, indicating considerable gaps in the current evaluation literature. A detailed breakdown of outcomes is provided below.

Table A1. Definitions of aid used in articles reviewed

Aid definition	# of Articles
ODA	7
Foreign aid (= ODA)	5
Health sector specific aid	4
ODA for HIV/AIDS	2
(Foreign) aid for health	2
Other definitions	7

Note: Two articles used multiple definitions of aid therefore #=27.

Infant health

Thirteen studies assessed the impact of ODA on infant mortality rates. Overall evidence of impact is mixed. Four studies find evidence that ODA significantly reduces IMR (Islam, 2003; Kotsadam *et al.*, 2018; Win and Cho, 2018; Akinlo and Sulola, 2019), with one additional study estimating DFID health programming alone to have resulted in 187,000 newborn lives saved between 2010 and 2014 (Friberg, Baschieri and Abbotts, 2017). However, three studies do not detect any significant effect of ODA on IMR in their analysis (Arndt, Jones and Tarp, 2015; Pallas and Ruger, 2017; Toseef, Jensen and Tarraf, 2019). The remaining studies report aid to significantly decrease IMR mostly in interaction with other factors, such as education (Mukherjee and Kizhakethalackal, 2013), the level of female empowerment (Montinola and Prince, 2018) or human rights commitments (Cole and Reynolds, 2019) in a country. One study reports that depending on the aid measure used, ODA had either no or a detrimental effect on IMR, while increasing aid volatility was associated with reductions in IMR (Wolf, 2007). Lastly, one study remains inconclusive due to internal contradictions (Irfan and Nehra, 2016).

Maternal health (incl. prenatal care and childbirth)

Of four studies assessing the impact of ODA on maternal mortality, one study finds evidence for ODA leading to a significant reduction in maternal mortality (Pickbourn and Ndikumana, 2016), while another study estimates DFID health and family planning programming to have saved 103,000 women's lives between 2010 and 2014 (Friberg, Baschieri and Abbotts, 2017). Two other studies show mixed results, with one study reporting contradictory effects depending on the type of lending provided by the World Bank (Coburn *et al.*, 2017), and another study finding that only aid allocated directly to the reproductive or maternal health sector reduces maternal mortality (Banchani and Swiss, 2019). Evidence for an impact of ODA on prenatal care provision remains inconclusive. One study did not observe an effect of ODA on prenatal care (Mukherjee and Kizhakethalackal, 2013), whereas another study reported that HIV aid improved prenatal care only in countries with low or medium HIV prevalence or low physician density (Grépin, 2012).

HIV/AIDS

Five articles assessed the effect of ODA on HIV/AIDS-related outcomes. Two studies report that ODA significantly reduces HIV/AIDS-related mortality (albeit only in the case of US bilateral aid in one study) (Nunnenkamp and Öhler, 2011; Hsiao and Emdin, 2015). Evidence for ODA lowering HIV/AIDS incidence is inconclusive, with one study supporting and another study refuting an effect (Nunnenkamp and Öhler, 2011; Lee, Yang and Kang, 2016). Two studies evaluating ODA's effect on HIV/AIDS prevalence find no evidence (Lee, Yang and Kang, 2016) and mixed evidence (Yogo and Mallaye, 2015) of a significant impact of ODA, respectively. Lastly, one study reports that increases in foreign assistance for HIV are significantly associated with increases in antiretroviral therapy coverage in 13 African countries (Bendavid *et al.*, 2010).

Family Planning

While outcomes evaluated varied, there appears to be some evidence of ODA impacting family planning in recipient countries. One study observes that ODA significantly reduces adolescent fertility rates (Zhuang, Wang and Daniels, 2020), while another study demonstrates that countries highly exposed to a withdrawal of US bilateral aid under the Mexico City Policy (MCP) experienced a significant concomitant decline in contraceptive use compared to countries with low exposure to the MCP (Brooks, Bendavid and Miller, 2019). Similarly, a third study finds evidence that USAID family planning funding significantly increased prevalence rates of modern contraceptives (Shepard *et al.*, 2003).

Abortion

Only one study evaluated the impact of the Mexico City Policy on abortion rates and concluded that withdrawal of US bilateral aid under the Mexico City Policy resulted in significantly increased abortion rates in highly exposed countries compared to countries with low exposure (Brooks, Bendavid and Miller, 2019).

Quality of Evidence

Overall, the quality of evidence for the effects of ODA on SRH outcomes was assessed as moderate. None of the studies included in this review were experimental in study design. Most studies (n=14) applied a fixed effects analysis using panel data, which is similar to the approach we adopt in our analysis. Three of studies could be described as quasi-experimental in nature, using a difference-in-difference analytical approach. Although they do not employ randomization, both fixed effects and DiD provide some evidence as to a possible causal relationship between ODA and SRH outcomes. The remaining studies were observational, except one which used a structural causal model. Out of the 25 studies that met

the eligibility criteria, all except one have been published in peer-reviewed journals. This lack of grey literature in the final review indicates that grey literature largely did not meet the eligibility criteria specified, with reported effects assessments being frequently qualitative or lacking in statistical analysis. The large differences between the studies in terms of study design, definition of ODA and the variety of outcomes measured make it difficult to say something conclusive about both the completeness and quality of the evidence.

Definition of Study Design Classification

Studies were classified into three categories according to their ability to make a causal claim as to the relationship between ODA and SRH outcomes.

Experimental – Studies employing an experimental study design with randomization. Able to make a causal claim. Considered strong evidence.

Non-Experimental – Studies lacking randomization, but employing a study design that allows to infer causality (e.g. quasi-experimental studies, use of causal models). Able to make a causal claim. Considered moderate evidence.

Observational – Studies that merely test for the association or correlation between ODA and SRH outcomes and do not provide any modelling. Unable to make a causal claim. Considered weak evidence.

Annex II. Results tables for the main FE analysis

Empirical strategy

As outlined in the main report we used fixed effect (FE) models as main estimation method. FE estimators address the threat of endogeneity from omitted variables bias. The main FE model takes the following form.

$$\text{SRH}it = \alpha it + \varphi \text{ODA}it + \beta Xit + \eta i + \upsilon t + \epsilon it \qquad (1)$$

The subscripts i and t denote country and year, respectively. SRH_{it} measures the SRH services of interest in the study. ODA_{it} measures the sectoral ODA disbursed to a country in a certain year (t). In the main model ODA is expressed in per capita terms to account for the effect of ODA after when controlling for the recipient countries' populations. φ_{it} is the main ODA effect estimate. X_{it} is a vector of country-level covariates that might impact SRH services in a country (i), as shown by previous studies. The country fixed effects (η_i) control for unobserved time-invariant factors at the country level. υ_t are the time fixed effects, which account for universal time trends experienced across countries. Finally, α_{it} and ϵ_{it} are the intercept and the idiosyncratic error term, respectively.

Table A1. The effect of health ODA on SRH services, summary of FE estimates

	Sectoral Health ODA, USD per capita (2020 constant)		
SRH service indicator	**SRH ODA**	**Total Health ODA**	**RH ODA**
Modern contraceptive prevalence	0.628***	0.242**	0.935
Skilled birth attendance	0.190*	0.059	0.902
ART coverage	0.531***	0.332***	0.575
Two-way FE	YES	YES	YES
Extended Controls	YES	YES	YES

Note: *** p<0.01, ** p<0.05, * p<0.1.

Model 1 was estimated using a linear-linear specification; thus, effect estimates represent the average percentage point change in service coverage associated with a 1 USD per capita increase in sectoral health ODA. The covariates GDP per capita, and population density (per sq. km) were log transformed to facilitate the interpretation of coefficients.

For each combination to ODA measure to SRH service indicator, the random-effect models were favored over the pooled OLS models based on the Breusch-Pagan Lagrange multiplier test. Moreover, the Durbin–Wu–Hausman test results suggested that FE models were preferred over the random-effects. All models were run with standard errors clustered at the country level, given significant results ($p<0.05$) from the Wald test for groupwise heteroskedasticity and Lagrange-Multiplier test for serial correlation. The tables below include the estimator selection procedures and relevant diagnostics.

Table A2. FE estimation of the effects of sectoral ODA on modern contraceptive prevalence (based on ODA disbursements per capita)

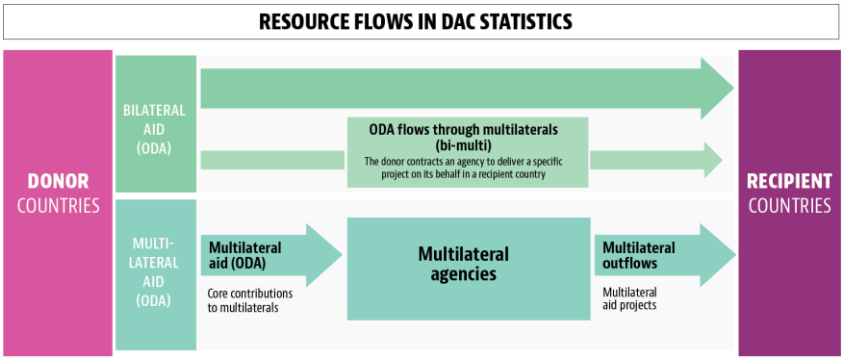
Annex III. Additional results

Based on the main FE estimation method, we conducted five additional investigations. First, we included an interaction term between ODA and countries' income classification in 2002 (as defined by the World Bank) to test for the effect of ODA on SRH services conditional on the baseline economic welfare of countries.

Second, we investigated whether ODA needs to have a certain volume, relative to government health expenditure, for a positive effect to occur. We created a variable ODA as share of GHE calculated by dividing sectoral ODA per capita (constant 2020 USD) by GHE per capita (current USD). Countries were classified into four categories, using the quantile values of the ODA/GHE variable as cut-off points. Quantiles were defined based on the relevant sample for each analysis. To spot differences between these categories, we included an interaction term between ODA disbursed and the categorical ODA/GHE variable.

Similarly, we investigated whether there is a difference in effect of health ODA depending on the volume of health ODA relative to total ODA received by a country. We created a variable health ODA as share of total ODA, calculated by dividing sectoral ODA per capita (constant 2020 USD) by total ODA per capita (constant 2020 USD). Quantile values of the health ODA/total ODA variable were used as cut-off points to create categories. To spot differences between the categories, we included an interaction term between health ODA disbursed and the categorical health ODA/total ODA variable.

Figure A1. Bilateral vs. multilateral ODA as defined in the OECD-CRS database



Source: OECD

Fourth, we investigated whether there were differences in ODA effectiveness over time, by including an interaction term between sectoral ODA and three-year periods. This could be indicative of a learning process in ODA utilization.

Fifth, we investigated whether the effectiveness of sectoral ODA differed depending on donor type by comparing the effects of ODA (all donors) to bilateral ODA and multilateral ODA. Bilateral ODA represents flows from official (government) sources directly to the recipient countries. Bilateral ODA includes resources (called non-core/multi-bi) channeled through national or international NGOs active in development to execute a specific project on behalf of the donor. Multilateral ODA represents flows from official (government) sources to ODA-eligible multilateral organizations, also referred to as core contributions. Donor countries typically not specify which projects and programmes are to be funded with these contributions and multilateral agencies use them for their own developmental programmes. Multilateral agencies also receive funds from other sources, not included in the ML ODA statistic (e.g., general public, philanthropy sources).

These five additional analyses were first estimated using the main FE models, with two-way FE (country, time) and time-variant controls i.e., lnGDP per capita, GHE/CHE, government effectiveness, control of corruption, ln population density, primary school enrolment, female labor market participation. Then, the effects were estimated by applying the FE estimator to three-year-averaged values of all variables (to account for the potential influence of missing data), resulting in six three-year time periods.

The results tables from the additional analysis are displayed below. First, we present the tables from the main FE estimation and then the results from the three-year averaged models.

Marginal effect of sectoral ODA on SRH services conditional on countries baseline income classification

Table A1. FE estimation – Marginal effect of ODA on modern contraceptive prevalence in each income group (based on main FE Model)

Annex IV. Sensitivity analysis

Our sensitivity analyses aim to account for shortcomings of the data and the main FE estimation. First, we investigate potential bias from measurement error and missing data. Second, we try to account for the influence of outlying observations with robust FE estimators. Third, we estimate the main model using alternative specifications (log-log, linear-log). Fourth, we investigate the potential of a delayed impact of ODA on service outcomes with a lagged independent variables (IVs) model. Finally, we implemented a dynamic FE estimator, the system-GMM estimator, to account for the potential endogeneity of the regressors.

For each of these approaches, we first provide a summary table showing the ODA effect estimates from the main model next to the effect estimates from the sensitivity analyses. Each summary table is then followed by complete tables, including parameter estimates and robust standard errors.

Sensitivity to missing data and measurement error

FE 3-Year-Averaged Variables	1.481	0.649	1.181

Note: All estimators include country and time fixed effects. All measures of health ODA are in USD per capita (constant 2020). Standard errors are clustered at the country level. *** p<0.01, ** p<0.05, * p<0.1. In the Interpolated Variables model, all covariates and the dependent variable (SRH service indicators) are interpolated with STATA command *ipolate*. In the 3-Year-Averaged Variables model, all variables are averaged over three years resulting in six 3-year periods.

FE estimator (linear-log, USD millions)	1.203	-0.224	2.004*
FE estimator (log-log, USD millions)	0.0606	0.00189	0.136***
RH care ODA			
Main FE estimator (linear, USD pc)	0.935	0.902	0.575
FE estimator (linear-log, USD millions)	1.676***	0.830**	0.711

Sectoral ODA	SRH service outcomes		
	Contraceptive Prevalence	Skilled birth attendance	ART coverage
FE estimator (log-log, USD millions)	0.0706***	0.0265***	0.0134

Note: All estimations include country and time fixed effects. Standard errors are clustered at the country level. *** p<0.01, ** p<0.05, * p<0.1. In the linear-log specification, all IVs are log-transformed, including ODA. The linear-log specification provides the absolute change in service coverage (percentage points) associated with a per cent change in ODA. In the log-log specification, all variables are log-transformed, including SRH service indicators. The log-log specification allows coefficients to be interpreted as elasticities, thus the percent change in service coverage associated with a percent change in ODA.

Dynamic FE model – System GMM

The relationship between service coverage and health ODA may be dynamic, meaning that previous SRH services coverage might be correlated with contemporary ODA allocation decisions. To account for the potential endogeneity of ODA (and covariates) due to this dynamic effect, we used a two-step system GMM estimator with country and time fixed effects on our data (Frees 2004, Cameron and Trivedi 2005). For this estimation, we used the community-contributed xtdpdgmm command in STATA (Kripfganz 2020).

The system-GMM estimator was applied to the three-year averaged data with six time periods, to limit bias from missing data and measurement error. Based on their suggested relevance from the main models, the following covariates were included in the system-GMM models; ln GDP pc, GHE/CHE, corruption control, ln population density, and primary school enrollment.

As a starting point, ODA was considered predetermined, and all other covariates were considered endogenous. Lagged forward-orthogonal-deviations (fod) of these variables were used as instruments for the current levels of the regressors. While first-differences (diff) are most commonly used, the fod-GMM estimator retains more information than the diff-GMM estimators in unbalanced panels (Kripfganz 2020), such as ours. Our initial candidate model included all available instruments for the fod-transformed models. The two-step system-GMM was implemented with robust and Windmeijer corrected standard errors and the instrument set was collapsed, to reduce the number of instruments. This was necessary given the relatively small number of countries (N) in our panel.

For each system-GMM model estimated, a Hansen test for overidentifying restrictions was conducted as well as AR(1) and AR(2) tests for first and second-order autocorrelation, respectively. Moreover, the Akaike (AIC) and Bayesian (BIC) information criteria

were computed to compare candidate models and support the specification search. Specifications of individual models were systematically adjusted (from the baseline choice) to fit the stringent identifying assumptions. For instance, we experimented with including a different number of instruments (e.g., limiting instruments to two-period lags). Also, we tested the models when classifying some of the covariates as pre-determined, and even exogenous.

In line with the main FE estimation, the results from the system-GMM estimation generally suggested positive associations between sectoral health ODA and SRH services. However, the magnitude and significance of these positive associations was highly sensitive to model specifications and variable classifications. The GMM modelling approach was designed to estimate models with relatively few time periods and large panels (N) and requires a quite large number of observations to provide robust estimates. Thus, it may not be ideal for our country-level panel data. The reduction in potential endogeneity bias from using the system-GMM estimator may come at the cost of loss in precision (Frees 2004).

TotH ODA as share of GHE (%)	2,016	71.9	1.181	7.87e-03	1161.4
SRH ODA as share of GHE (%)	1,969	26.8	0.488	4.84e-04	505.1
RH care ODA as share of GHE (%)	1,905	5.28	0.132	-0.0416	194.9

Note: Table A1 presents summary statistics for the 119 LLMIC over the period 2002–2020. The unit of observation is country-year. The panel is unbalanced. Regarding negative ODA values, loan repayments are recorded as negative and deducted from ODA. In some cases, loan repayments are higher than new ODA and net ODA will show as a negative number. Data sources: OECD-CRS, WGI, WDI.

Table A2. Between and within country variation for key variables

Variable		Mean	Std. Dev	Min.	Max	Observations
Total Health ODA, millions USD	overall	113.055	185.913	0.014	1345.917	N = 2235

	within		16.032	23.364	139.081	n = 116
	between		7.748	53.591	145.932	T-bar = 14.836
Female labor market participation rate (% of female pop. ages 15+)	overall	50.872	19.0508	6.081	87.812	N = 2166
	within		18.993	10.025	84.2072	n = 114
	between		2.2795	39.730	65.8904	T-bar = 19

Note. The unit of observation is country-year. The standard deviations show that, while there is variance across countries, there is substantial within-country variation in SRH services outcomes, health ODA received, and covariates. Such within-country variability is required to be able to apply FE models.
Data sources: OECD-CRS, WGI, WDI.

Table A3. Definitions and sources of variables and indicators

	Variable	Indicator (unit of measurement)	Source (period)	Comment
Independent variables	Health ODA	Health ODA disbursement (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 120
ODA collected for multilateral, bilateral and all donors	SRH ODA	Population programs & policies and reproductive health ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 130
	PP ODA	Population policy & programs ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 13010
	RH ODA	Reproductive healthcare ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 13020
	FP ODA	Family planning ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 13030
	STD ODA	STD-control ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 13040
	PD ODA	Personnel development ODA (constant 2020 USD)	OECD-CRS (2002-2020)	Purpose code 13081
Dependent variables	SBA	Births attended by SBA (% of live births)	WDI (2002-2020)	
	Contraceptive	Contraceptive prevalence, any modern methods - % of married women (aged 15-49)	WDI (2002-2020)	
	ART coverage	Antiretroviral therapy coverage (% living with HIV)	WDI (2002-2020)	

	Variable	Indicator (unit of measurement)	Source (period)	Comment
Control variables	GDP per capita	GDP per capita (constant 2017 international, adjusted for purchasing power parity)	WDI (2002-2020)	PPP
	GHE per capita	Domestic general government health expenditure per capita (current US$)	WDI (2002-2020)	
	IG	Income classification	World Bank (2002-2020)	L, LM, UM, H
	GHE as share of CHE	Domestic general government health expenditure (% of current health expenditure)	WDI (2002-2019)	
	Corruption Control	Control of corruption estimate, -2.5 (low) to 2.5 (high)	WGI (2002-2020)	Re-scaled 0 (low) to 5 (high)
	Government Effective	Government effectiveness estimate, -2.5 (low) to 2.5 (high)	WGI (2002-2020)	Rescaled from 0 (low) to 5 (high)
	Primary Schooling	Enrolment rate, primary (% gross)	WDI (2002-2020)	
	Female labor part.	Labor force participation rate, female (% of ages 15+)	WDI (2002-2020)	
	Population Density	Population density (pop. per km^2 land)	WDI (2002-2020)	
	Population	Total population	WDI (2002-2020)	

Note: Corruption Control and Government effectiveness estimates were re-scaled from 0-5 to be able to apply logarithmic transformations.
